

Direct Drive DC Torque Motors

The Direct Drive DC torque motor is a servo actuator which can be directly attached to the load it drives. It has a permanent magnet (PM) field and a wound armature which act together to convert electrical power to torque. This torque can then be utilized in positioning or speed control systems. In general, torque motors are designed for three different types of operation:

- High stall torque (“stand-still” operation) for positioning systems
- High torque at low speeds for speed control systems, and
- Optimum torque at high speed for positioning, rate, or tensioning systems.

Direct drive torque motors are particularly suited for servo system applications where it is desirable to minimize size, weight, power and response time, and to maximize rate and position accuracies.

Frameless motors range from 28.7mm (1.13in) OD weighing 1.4 ounces (.0875 lbs) to a 4067 N-m (3000 lb-ft) unit with a 1067mm (42in) OD and a 660.4mm (26in) open bore ID. Housed motors range from a one inch cube design with 0.049 N-m (7 oz-in) peak torque to any of the frameless motors housed to customer specifications with integral DC tachometers, resolvers, encoders and shaft configurations.

Direct Drive DC Torque Motors

INTRODUCTION

Advantages of Direct Drive DC Torque Motors

High Torque-to-Inertia Ratio at the Load

A direct drive motor provides the highest practical torque-to-inertia ratio where it counts—at the load. In a geared system, reflected output torque is proportional to the gear reduction while reflected output inertia is proportional to the square of the gear reduction. Thus, the torque-to-inertia ratio in a geared system is less than that of a direct drive system by a factor equal to the gear-train ratio. The higher torque-to-inertia ratio of direct drive motors makes them ideally suited for high acceleration applications with rapid starts and stops.

High Torque-to-Power Ratio

Most torque motors are designed with a large number of poles and a high volume of copper to achieve a high torque-to-power ratio. Thus, input power requirements are usually low.

Low Electrical Time Constant

Typical torque motor design features — such as high-level magnetic saturation of the armature core and the use of a large number of poles — keep armature inductance at a very low value. Consequently, the electrical time constant (the ratio of armature inductance to armature resistance) is very low, providing excellent command response at all operating speeds.

High Linearity

In a DC torque motor, torque increases directly with input current at all speeds and angular positions. The theoretical speed-torque characteristic is a set of parallel straight lines (Figure 1). This torque linearity is maintained even at low excitation, assuring no dead-band created by torque non-linearities for all input currents up to the peak rating of the motor.

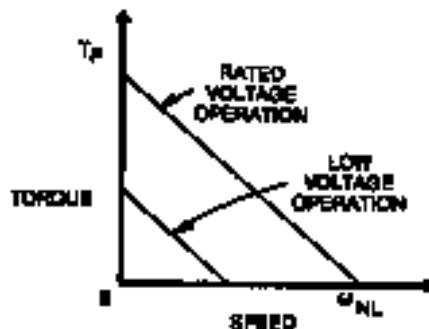

Figure 1

Reliability and Long Life

Basic simplicity and an absolute minimum of moving parts make a torque motor inherently reliable. Extensive design and production experience have placed Kollmorgen's motors in critical applications where high performance motion control is required for the last three decades. These include applications in all conditions and environments, ranging from thousands of feet underwater to years of unattended operation in outer space. Brushes are capable of operating in a hard vacuum with "high altitude" additives.

High Resolution

The direct drive use of torque motors allows them to position a shaft more precisely than a geared system. With typical gearing, the backlash contributes to a "dead zone" which falls in the region of the system null point and reduces positional accuracy. In a direct drive system, however, the positional accuracy is, in practice, limited only by the error-detecting transducer system.

Compact, Adaptable Design

Frameless torque motors are built to be "designed-in" as an integral part of a system, thus saving the weight and space associated with conventional motor frames or housings. This frameless design allows the motors to be mounted anywhere along the driven shaft. The "pancake" configuration (thin, compared to diameter) minimizes the volume required for mounting and offers a convenient packaging arrangement for combinations of torque motors and tachometer generators.

Kollmorgen also supplies housed motors, complete with housing, shaft and bearings for use in similar applications.

Direct Drive DC Torque Motors

INTRODUCTION

System Performance Characteristics

The same features which give torque motors an advantage over other types of servo actuators also allow the designer to obtain the following system performance characteristics.

High Servo Stiffness

The direct-drive torque motor is coupled directly to the load, thus eliminating gears and backlash errors. The resulting high coupling stiffness and associated high mechanical resonance frequency yield high servo stiffness.

Fast Response

The low electrical time constant of torque motors allows torque to develop very rapidly when voltage is applied. This fast response is an important aid to servo stiffness.

High Resolution

The direct-drive use of torque motors allows them to position a shaft more precisely than a geared system. With typical gearing, the backlash contributes to a "dead zone" which falls in the region of the system null point and reduces positional accuracy. In a direct-drive system, however, the positional accuracy is, in practice, limited only by the error-detecting transducer system.

Low Speeds with High Accuracy

Because of the high coupling stiffness and high resolution of direct-drive torque motors, it is possible to achieve high accuracy at low speeds. An example is a table for testing rate and integrating gyros. This table has a speed range of 0.017 to 100 rpm with absolute instantaneous accuracy over this speed range of 0.1 percent.

Smooth, Quiet Operation

Torque motors exhibit smooth, quiet operation when they are run at low speeds. They typically have a large number of slots per pole to reduce cogging and allow for smooth operation.

Motor Selection

Frameless or Housed?

Both the torque motor section and the servo motor section of this catalog are divided into subsections of frameless motors and housed motors.

Housed motors have a traditional configuration including frame, bearings, and shaft. In use, the housed motor shaft is coupled to the system element being driven. Housed motors are ideal for use in harsh environments or other applications requiring totally closed units.

The frameless motor concept was developed to meet the need for motors with a large hole through the center. This need is still one of the main reasons that the large diameter, narrow width frameless configuration is often selected over the traditional housed configuration. The large rotor bore can be used as a route for lead wires, as a mounting area for other hardware such as tachometer generators or resolvers, or as an optical path.

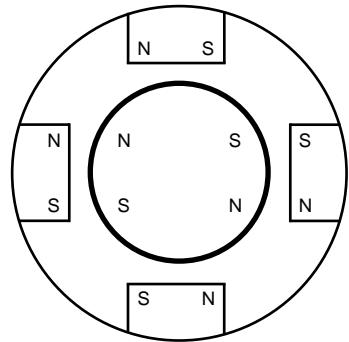

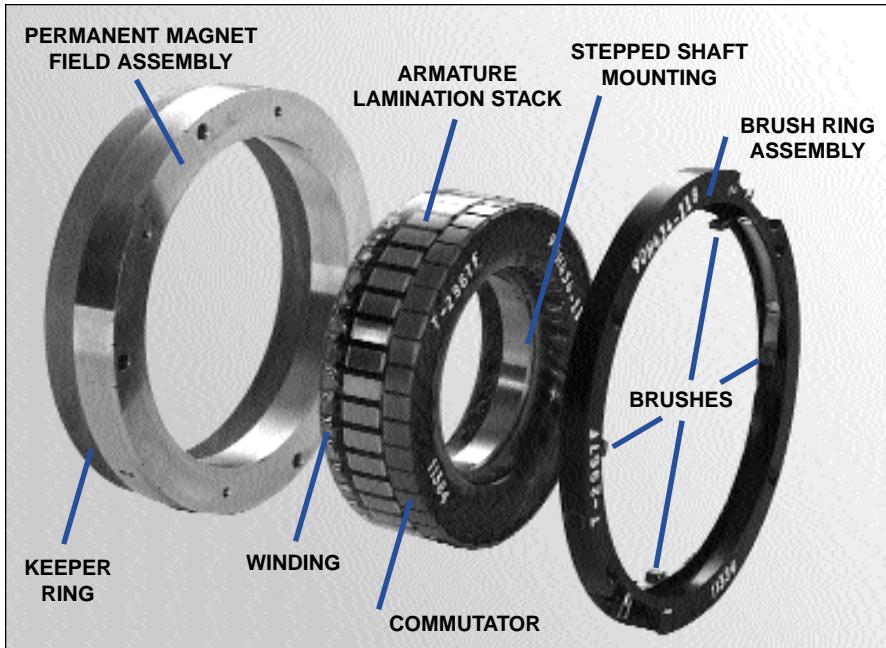

Frameless motors are built to be "designed in" as an integral part of the system hardware. They are generally supplied as three separate components: stator (field) assembly, rotor (armature) assembly and brush ring or brush segment assembly (See Figures 2, 3). The frameless motor can be integrated into the customer hardware rather than coupling a motor shaft to the element being driven. This allows significant savings in space and weight over housed motors by eliminating the motor housings, bearings and shaft. Also, since the frameless motor can be mounted on the driven shaft, the coupling stiffness is improved. The backlash normally associated with couplings or gear trains is eliminated from the drive system.

Torque Motor or Servo Motor?

A torque motor is typically described as having a "pancake" configuration, i.e., a large diameter and a narrow width. This configuration generally has a large number of poles to increase the torque available in a given volume. This large number of poles, however, also causes more commutation arcing as speed increases than for a motor with few poles. Torque motors are most commonly used in positioning and slow-speed rate applications where commutation is not a limitation. A servo motor is characterized by a long, small diameter configuration. Lengthening a motor while maintaining a small diameter allows a significant increase in torque while minimizing the increase in rotor inertia. The end result is an improved mechanical time constant and, therefore, improved motor response. Servo motors are most commonly used in running applications where good high-speed commutation is demanded and operation at or near stall is not required.

Alnico and rare earth
magnet designs

Direct Drive DC Torque Motors

INTRODUCTION

Magnet Material

The motors are manufactured with one of two magnet materials: Alnico or rare earth (Samarium Cobalt and Neodymium-Iron-Boron). Model numbers preceded by "T", "NT", or "OT" have Alnico magnets and models preceded by "QT" have rare earth magnets. These magnet materials have different characteristics which determine their suitability for various applications.

Performance: A major advantage of rare earth magnet motors is stability of magnetic characteristics in overcurrent conditions. In Alnico magnet motors, exceeding the rated current I_p to develop more torque may demagnetize the permanent magnet field and cause a permanent reduction in torque per unit current. The degree of demagnetization is determined by the magnitude of the overload current. In rare earth magnet units, currents in excess of I_p can be applied for short duration to develop higher torque without demagnetization of the PM field. The limits now become primarily the thermal capacity of the motor and the current density rating of the brushes.

Rare earth magnet motors that are designed to have comparable resistance to similar Alnico designs will generally have a lower inductance value than the Alnico design. Thus, the electrical time constant of rare earth units is normally lower than Alnico units, allowing more rapid system response.

Installation: Alnico magnet motors require a keeper ring or keeper segments to provide a return flux path for the field when the rotor is not in place. Removing or shifting the keeper before inserting the armature into the field will cause significant degradation of performance. In rare earth magnet motors the magnet material has much higher intrinsic coercive force. This feature makes the field assembly immune to the effects of an open magnetic circuit and therefore a keeper is not required. Eliminating the keeper can simplify installation considerably.

The mounting surfaces for frameless Alnico magnet motors must be made of non-magnetic material such as aluminum, brass or non-magnetic stainless steel. The minimum thickness of non-magnetic material required to separate the field structure from magnetic material is one quarter inch. Rare earth motors may be mounted in magnetic or non-magnetic housings.

Rare earth magnet material is more brittle than Alnico, and care must be exercised to avoid chipping or cracking. Because rare earth motors are designed with the magnets on the inner diameter of the stator assembly facing the armature, extra care must be taken when inserting the armature into the field assembly. Most rare earth units have larger radial air gaps than similar size Alnico units. The larger air gap of rare earth units makes rotor-to-stator concentricity less critical (See Figure 4).

*Note: Metric weight expressed in Kg.

TABLE OF STANDARD OPTIONS

These standard options allow our customers to modify existing catalog motors to achieve the features as described below. Please consult factory for application information.

Higher Torque

Magnet Materials	Alnico Neodymium-Iron-Boron Samarium Cobalt
Lamination Materials	Silicon Steel Vanadium Permedur
Magnetic pole Count	Up to 2 times the catalog model. <i>Consult factory</i>

Higher Power

Stack Length Increase (Magnets & Laminations)	0.25 inches to 3 inches (motor length increases the same as the stack length)
--	--

Speed/Torque Changes

Winding Wire Gages	#20 - 28 AWG (<i>standard</i>) #00-48 AWG
--------------------	--

Installation Features

Shaft Geometry	Round (<i>standard</i>) Hollow, keyway, flat or integral gear
Mounting	Bolt hole diameter and circumferential pattern (<i>customer specified</i>)
Lead Length	18 inches (<i>standard</i>) 7 to 48+ inches (<i>customer specified</i>)
Lead Color	Red/White/Black (<i>standard</i>) Colors to be specified by customer

Durability

Varnishes or Encapsulation	115°C (<i>standard</i>) 200°C
----------------------------	------------------------------------
